Transfer canvas: a confidence signal for your LLM-judged task

Names _____

Field / lab _____

Pick a task from **your own research** where an LLM decides whether some **evidence** satisfies some **rule**. Sketch how you would know when to trust its verdict. Be concrete: names of datasets, numbers, layers.

1 Your LLM-judged task

What is judged? What are the **rules** (criteria, rubric, policy)? What is the **evidence** (documents, code, transcripts)? Which judge model?

2 Ground truth

Where do correct labels come from (experts, past audits, benchmark)? **How many** labelled cases can you get? Inter-rater agreement?

3 Confidence signal

☐ verbalized ☐ token probability

☐ probe on layer _____ ☐ other _____

Why this one? What does it cost per verdict? Which token position do you read?

4 Threshold policy

Target **error among auto-accepted** verdicts: _____ %

Expected **coverage** (share not sent to a human): _____ %

How will you pick the threshold (held-out set, conformal)?

5 Grounding check

Which **intervention** shows the verdict depends on the **right** evidence? (remove / patch / contradict a sentence, swap a rule clause). What result would worry you?

6 Distribution-shift test

What is **new** in deployment (new rules, new clients, new document style, new language)? Which slice do you hold out to test that the signal transfers?

7 Risks and limits

When could a well-calibrated score still mislead you? Who is hurt by an **escape** (a wrong verdict that skips review)?

8 First experiment I'll run next week

One sentence: model, data, signal, metric, and what result would make you continue or stop. **Due by:** _____
